COMP2240 - Operating Systems
Workshop 1
Topics: Hardware Review & Operating System Overview

1. Consider a hypothetical 32-bit microprocessor having 32-bit instructions composed of two fields (Figure 1). The first byte contains the opcode and the remainder an immediate operand or an operand address.
   a) What is the maximum directly addressable memory capacity (in bytes)?
   b) Discuss the impact on the system speed if the microprocessor bus has
      I.   32-bit local address bus and a 16-bit local data bus, or
      II. 16-bit local address bus and a 16-bit local data bus.
   c) How many bits are needed for the program counter and the instruction register?

0	7	8	31
Opcode		Operand or Address	
   Figure 1: Instruction Format of the 32-bit Hypothetical Machine

2. A DMA module is transferring characters to main memory from an external device transmitting at 9600 bits per second (bps). The processor can fetch instructions at the rate of 1 million instructions per second.
   By how much will the processor be slowed down due to the DMA activity? (You can ignore the data read/write operations and assume that the processor only fetches instructions.)

3. Suppose that a large file is being accessed by a computer memory system comprising of a cache and a main memory. The cache access time is 60ns. Time to access main memory (including cache access) is 300ns. The file can be opened either in read or in write mode. A write operation involves accessing both main memory and the cache (write-through cache). A read operation access either only the cache or both the cache and main memory depending upon whether the access word is found in the cache or not. It is estimated that read operations comprise of 80% of all operations. If the cache hit ratio for read operation is 0.9, what is the average access time of this system?

4. How are iOS and Android similar? How are they different?

5. In a batch operating system, three jobs J1, J2, and J3 are submitted for execution. Each job involves and I/O activity, a CPU time, and another I/O activity.
   Job J1 requires a total of 20ms, with 2ms CPU time.
   J2 requires 30ms total time with 6ms CPU time.
   J3 requires 15ms total time with 3ms CPU time.
   What will be the CPU utilization for **uniprogramming** and **multiprogramming**?

Supplementary problems:

S1. Direct memory access (DMA) is used for high-speed I/O devices in order to avoid increasing the CPU's execution load.
- a) How does the CPU interface with the device to coordinate the transfer?
- b) How does the CPU know when the memory operations are complete?
- c) The CPU is allowed to execute other programs while the DMA controller is transferring data. Does this process interfere with the execution of the user programs? If so, describe what forms of interference are caused.

S2. Suppose a stack is to be used by the processor to manage procedure calls and returns. Can the program counter be eliminated by using the top of the stack as a program counter?

S3. Consider a hypothetical microprocessor generating a 16-bit address (e.g., assume that the program counter and the address registers are 16 bits wide) and having a 16-bit data bus.
- a) What is the maximum memory address space that the processor can access directly if it is connected to a "16-bit memory"?
- b) What is the maximum memory address space that the processor can access directly if it is connected to an "8-bit memory"?
- c) What architectural features will allow this microprocessor to access a separate "I/O space"?
- d) If an input and an output instruction can specify an 8-bit I/O port number, how many 8-bit I/O ports can the microprocessor support? How many 16-bit I/O ports?

Explain.

S4. Suppose that we have a multiprogrammed computer in which each job has identical characteristics. In one computation period, T, for a job, half the time is spent in I/O and the other half in processor activity. Each job runs for a total of N periods. Assume that a simple round-robin scheduling is used, and that I/O operations can overlap with processor operation. Define the following quantities:
- Turnaround time = actual time to complete a job
- Throughput = average number of jobs completed per time period T
- Processor utilization = percentage of time that the processor is active (not waiting)

Compute these quantities for one, two, and four simultaneous jobs, assuming that the period T is distributed in each of the following ways:
- a) I/O first half, processor second half

I/O first and fourth quarters, processor second and third quarter
